

Architecture and Design

Table of Contents

1. Maven modules	2
1.1. core	2
1.2. core/mavendeps	4
1.3. core/mavenplugins	6
1.4. archetypes	6
2. Metamodel	8

This guide describes the internal architecture and design of the framework.

Chapter 1. Maven modules

```
adocs/
└── documentation/
    └── template/
core/          # see 'core', below
example/       # see 'archetypes', below
scripts/
```

1.1. core

The core modules

All of these have the same Maven **groupId**, namely `org.apache.isis.core`.

```
core/
├── .m2/                      # used in gitlab CI
├── applib/                   # isis-core-applib
├── commons/                  # isis-core-commons
├── integtestsupport/         # isis-core-integtestsupport
├── log4j/                     # isis-core-log4j
├── maven-plugin/             # see 'maven plugins', below
├── mavendeps/                # see 'mavendeps', below
├── runtime/                  # isis-core-runtime
├── schema/                   # isis-core-schema
├── security/                 # isis-core-security
├── security-shiro/           # isis-core-security-shiro
├── specsupport/              # isis-core-specsupport
├── unittestsupport/           # isis-core-unittestsupport
├── unittestsupport-test/      # isis-core-unittestsupport-test

└── wrapper/                  # isis-core-wrapper
```

Table 1. core maven modules

Module	Description
<code>isis-core-applib</code>	Core application library.

Module	Description
<code>isis-core-integtestsupport</code>	Integration test support. Application integration tests typically extend from adapter superclasses defined in this module.
<code>isis-core-log4j</code>	Configures Log4j as the logging framework
<code>isis-core-metamodel</code>	<p>The classes that make up the metamodel which is used to render the UI.</p> <p>See the section below which also includes a simplified UML diagram of these classes.</p>
<code>isis-core-runtime</code>	The classes that make up runtime management and persistence of domain objects, as well as framework for security (concepts of authentication or authorisation).
<code>isis-core-schema</code>	Defines XSDs and generated classes that capture commands and interactions in XML form.
<code>isis-core-security</code>	<p>Defines a "bypass" implementation of security, for prototyping only.</p> <p>Using this implementation, any user/password is accepted and</p>
<code>isis-core-security-shiro</code>	Defines an implementation of security authentication which delegates to Apache Shiro.
<code>isis-core-specsupport</code>	Application BDD specs typically inherit from classes defined in this module.
<code>isis-core-unittestsupport</code>	Application unit tests may use some of the utilities defined in this module.
<code>isis-core-viewer-restfulobjects-applib</code>	Defines a client-side Java library for interacting with the REST API exposed by the Restful Objects viewer.
<code>isis-core-viewer-restfulobjects-rendering</code>	<p>Provides a <code>RepresentationService</code> API and a lower-level <code>ContentNegotiationService</code> API, along with implementations of each.</p> <p>These implementations provide support for the representations defined by Restful Objects spec v1.0, as well as a number of other Apache Isis-specific representations.</p>

Module	Description
<code>isis-core-viewer-restfulobjects-server</code>	<p>Defines the JAX-RS resources supported by the Restful Objects viewer.</p> <p>These parse the input, delegate to the runtime for a response, and hand control to the rendering module to generate a representation.</p>
<code>isis-core-viewer-wicket-applib</code>	<p>Currently just defines <code>WicketDeveloperUtilitiesService</code>, for clearing the cache.</p>
<code>isis-core-viewer-wicket-impl</code>	<p>The top-level integration with Wicket, for example defining the Apache Isis-specific implementations/subclasses of the Wicket APIs for application, web session, localizer and request cycle.</p> <p>Also defines registries of pages and components, as well as a number of domain services and mixins (for use by applications) that are only available within the Wicket viewer.</p>
<code>isis-core-viewer-wicket-model</code>	<p>Serializable mementos representing the state of runtime domain objects (or their individual members).</p>
<code>isis-core-viewer-wicket-ui</code>	<p>UI components that render the moduls.</p>
<code>isis-webdocker</code>	<p>Creates a Docker image for Tomcat that also contains the Apache Isis libraries, thereby enabling "skinny war" support.</p>
<code>isis-core-webserver</code>	<p>For development within an IDE, provides a utility class to bootstrap the application (using Jetty).</p>
<code>isis-core-wrapper</code>	<p>Provides an implementation of the <code>WrapperFactory</code> domain service.</p>

1.2. core/mavendeps

The `core/mavendeps` modules ...

All of these have the same Maven `groupId`, namely `org.apache.isis.mavendeps`.

mavendeps Modules

```
core
└── mavendeps/
    ├── isis-mavendeps-intellij/      # isis-mavendeps-intellij
    ├── isis-mavendeps-testing/       # isis-mavendeps-testing
    └── isis-mavendeps-webapp/        # isis-mavendeps-webapp
```

Table 2. core/mavendeps maven modules

Module	Description
isis-mavendeps-intellij	Defunct.
isis-mavendeps-testing	<p>Aggregates dependencies on various test-scope plugins useful for unit- and integration testing a module. These include Apache Isis' own <code>unittestsupport</code>, <code>integtestsupport</code> and <code>specsupport</code> modules, as well as a number of common testing/mocking/assertion libraries.</p> <p>These can then be included using a single dependency declaration:</p> <pre><dependencies> <dependency> <groupId>org.apache.isis.mavendeps</groupId> <artifactId>isis-mavendeps-testing</artifactId> <type>pom</type> <scope>test</scope> </dependency> </dependencies></pre>
isis-mavendeps-webapp	<p>Aggregates dependencies on Apache Isis runtime itself when used within a webapp.</p> <p>These can then be included using a single dependency declaration:</p> <pre><dependencies> <dependency> <groupId>org.apache.isis.mavendeps</groupId> <artifactId>isis-mavendeps-webapp</artifactId> <type>pom</type> </dependency> </dependencies></pre>

1.3. core/mavenplugins

There is a single Maven plugin module. Its Maven `groupId` is `org.apache.isis.tools`.

Plugin Modules

```
core/
└── maven-plugin/          # isis-maven-plugin
```

Module	Description
<code>isis-maven-plugin</code>	Code to build a maven plugin for the build. This plugin can validate the metamodel and generate Swagger specs for a domain model as part of the application's build pipeline.

1.4. archetypes

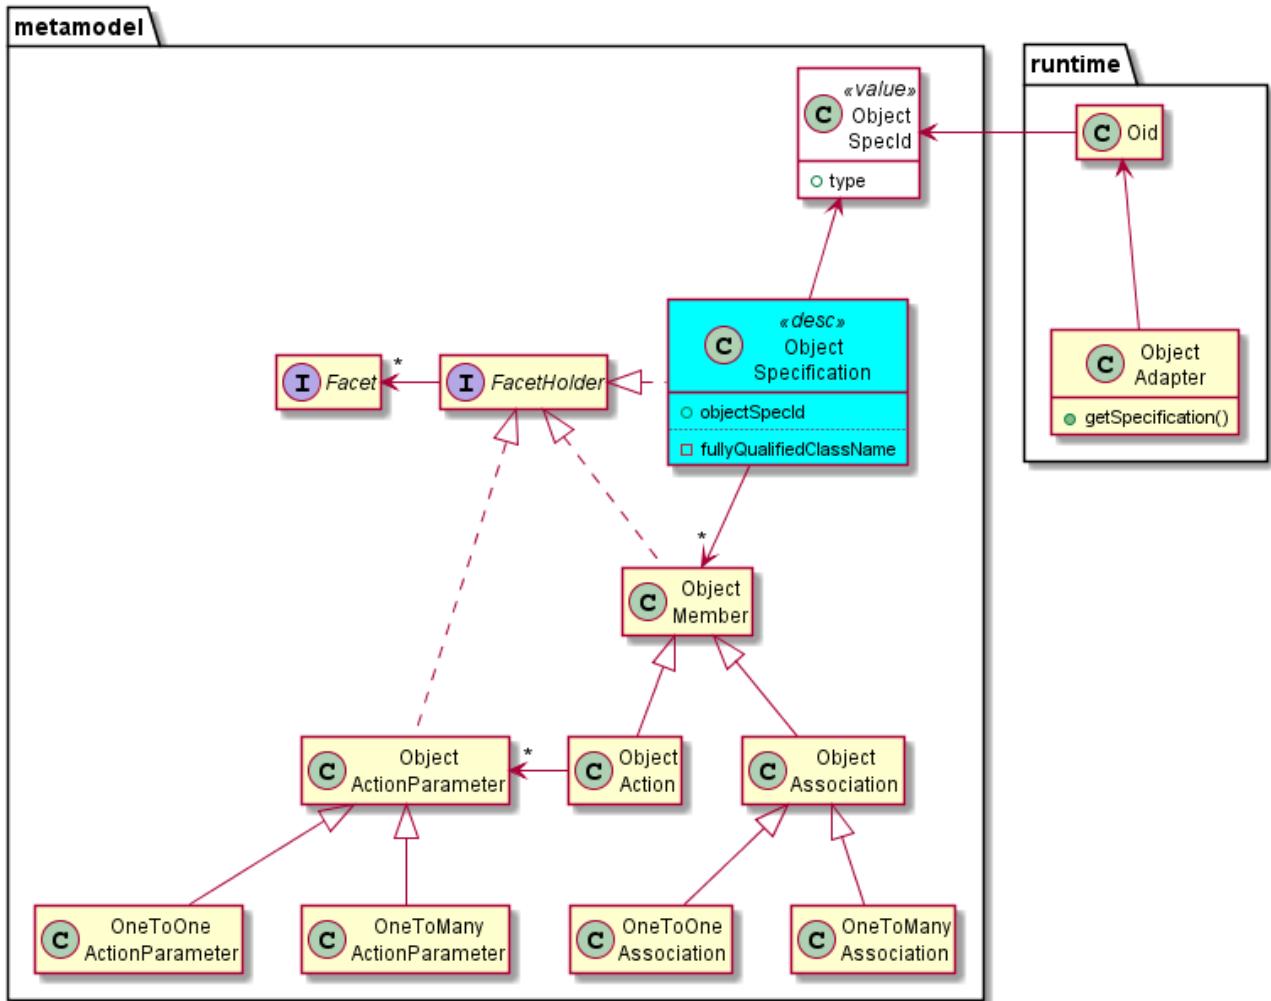

```
example/
├── application/
│   ├── helloworld/      # org.apache.isis.example.application:helloworld
│   └── simpleapp/        # org.apache.isis.example.application:simpleapp
│       ├── application/  # org.apache.isis.example.application:simpleapp-
application
│       └── module-simple/ # org.apache.isis.example.application:simpleapp-module-
simple
└── archetype/
    ├── helloworld/      # org.apache.isis.archetype:helloworld-archetype
    └── simpleapp/        # org.apache.isis.archetype:simpleapp-archetype
```

Module	Description
<code>helloworld</code>	An example application as a single Maven module, including domain classes themselves plus code to bootstrap Apache Isis. This is reverse engineered into the "helloworld" archetype.
<code>simpleapp</code>	The top-level aggregator module for the "simpleapp" example application. This is an extended version of helloworld, providing more structure (separating out domain model into modules) as well as unit tests, integration tests, BDD specs and fixtures. The simpleapp modules in aggregate are reverse engineered into the "simpleapp" archetype.

Module	Description
<code>simpleapp-application</code>	Defines the contents of the "simpleapp" application using Apache Isis-defined classes, as well as globally scoped domain services and the home page.
<code>simpleapp-module-simple</code>	Contains the domain model for a single module. The intention is to allow this module structure to be copied so that the developer can easily create further modules as their app increases in size.
<code>simpleapp-webapp</code>	Bootstraps Apache Isis as a webapp.
<code>helloworld-archetype</code>	Helloworld archetype, reverse engineered from the "helloworld" application (above).
<code>simpleapp-archetype</code>	Simpleapp archetype, reverse engineered from the "simpleapp" application (above).

Chapter 2. Metamodel

The diagram below shows a simplified version of Apache Isis' internal metamodel.

where in the **metamodel** package:

ObjectSpecification

is equivalent to `java.lang.Class`

ObjectSpecId

is a value object equivalent to the `@DomainObject#objectType` or `@DomainService#objectType` attribute

OneToOneAssociation

represents a scalar property

OneToManyAssociation

represents a collection

ObjectAction

represents an action (with multiple parameters, either scalar or list)

and in the **runtime** package:

Oid

is equivalent to the applib [Bookmark](#)

and appears in URLs in the Wicket and Restful Objects viewers

ObjectAdapter

is equivalent to [java.lang.Object](#)
